FAQ

Q1: What is the difference between free and forced vibrations?

A1: Free vibrations occur when a system oscillates without any external force after being initially disturbed. The frequency is determined by the system's inherent properties (mass, stiffness, damping). Forced vibrations occur when a system is subjected to a continuous external force. The frequency of oscillation is determined by the external force's frequency, and the amplitude depends on the

relationship between the forcing frequency and the system's natural frequency.

Q2: What is resonance, and why is it important to avoid it?

A2: Resonance occurs when the frequency of an external force matches a system's natural frequency, resulting in dramatically increased amplitude of vibrations. This can lead to structural failure, excessive wear and tear, and even catastrophic collapse in extreme cases. Engineers must carefully consider the system's natural frequencies and avoid excitation at these frequencies.

Q3: How does damping affect vibration?

A3: Damping dissipates energy from a vibrating system, reducing the amplitude of oscillations over time. Different types of damping (viscous, Coulomb, hysteretic) have different characteristics and impact the system differently. Proper damping design is crucial to control unwanted vibrations.
